

Question 1

Solution

a.

(i) Total number of test conducted = $T(s)$.

□

Question 2

To derive the PDF of random variable $Z = XY$, where X and Y are independent random variables with known PDFs $f_X(x)$ and $f_Y(y)$

Solution

$$\begin{aligned} P(XY \leq z) &= F_Z(z) \\ &= \int_{-\infty}^z f_Z(z) dz \end{aligned}$$

Probability that variable Y lies between y and $y + dy$

$$P(y \leq Y \leq y + dy) = f_Y(y) dy$$

for some y .

Now, for a fixed value of y , we have

$$P(XY \leq z | Y = y)$$

For $y > 0$,

$$P(XY \leq z | Y = y) = F_X\left(\frac{z}{y}\right)$$

$$P(Xy \leq z) = F_X\left(\frac{z}{y}\right) P(Y = y)$$

For $y < 0$,

$$P(XY \leq z | Y = y) = 1 - F_X\left(\frac{z}{y}\right)$$

$$P(Xy \leq z) = (1 - F_X\left(\frac{z}{y}\right)) P(Y = y)$$

and for $y = 0$,

$$P(XY \leq z | Y = 0) = \int_0^{\infty} f_Z(z) dz$$

$$P(XY \leq z) = \left(\int_0^{\infty} f_Z(z) dz \right) P(Y = 0)$$

So, we need to integrate on all possible values of y . Using the value of $P(Y = y)$, we can write

$$F_Z(z) = \int_{-\infty}^0 (1 - F_X\left(\frac{z}{y}\right)) f_Y(y) dy + \int_0^{\infty} F_X\left(\frac{z}{y}\right) f_Y(y) dy + \left(\int_0^{\infty} f_Z(z) dz \right) P(Y = 0)$$

Put $P(Y = 0) = 0$.

Now, differentiating w.r.t z , we get

$$f_Z(z) = \int_{-\infty}^0 -\frac{1}{y} f_X\left(\frac{z}{y}\right) f_Y(y) dy + \int_0^{\infty} \frac{1}{y} f_X\left(\frac{z}{y}\right) f_Y(y) dy + 0$$

or

$$f_Z(z) = \int_{-\infty}^{\infty} \frac{1}{|y|} f_X\left(\frac{z}{y}\right) f_Y(y) dy$$

which is the required PDF of Z .

Conclusion : The PDF of the product of two independent random variables X and Y is given by the integral formula :

$$f_Z(z) = \int_{-\infty}^{\infty} \frac{1}{|y|} f_X\left(\frac{z}{y}\right) f_Y(y) dy$$

Question 3

Solution

The correct estimate for $E(X)$ is: $\hat{x} = \frac{1}{n} \sum_{i=1}^n x_i$

Reason:

$$\begin{aligned} E(\hat{x}) &= \frac{\sum_{i=1}^n E(x_i)}{n} \\ &= \frac{nE(x_i)}{n} = E(x_i) = E(X) \end{aligned}$$

But when we talk about the estimate

$$\hat{x} = \frac{1}{n} \sum_{i=1}^n f_X(x_i) x_i$$

It does not give an expected estimate for $E(X)$.

$$E(x f_X(x)) = \int_{-\infty}^{\infty} x f_X(x)^2 dx \neq E(X)$$

Estimate of \hat{x} using the second formula will be

$$\begin{aligned} E(\hat{x}) &= \frac{\sum_{i=1}^n E(f_X(x_i) x_i)}{n} \\ &= \frac{nE(f_X(x_i) x_i)}{n} = E(f_X(x_i) x_i) = \int_{-\infty}^{\infty} x f_X(x)^2 dx \\ &\neq E(X) \end{aligned}$$

Hence, we have shown the correct estimate for $E(X)$ will be $\hat{x} = \frac{1}{n} \sum_{i=1}^n x_i$ by showing that the other formulae is estimating the expectation for some other random variable. \square

Question 5

Solution

$$P(X \geq x) \leq e^{-tx} \phi_X(t)$$

for $t > 0$ and

$$P(X \leq x) \leq e^{-tx} \phi_X(t)$$

for $t < 0$, where $\phi_X(t)$ is the MGF of X .

For a continuous random variable X , we have

$$\phi_X(t) = E[e^{tX}] = \int_{-\infty}^{\infty} e^{tx} f_X(x) dx$$

where $f_X(x)$ is the PDF of X .

e^{tx} is strictly increasing for $t > 0$ and strictly decreasing for $t < 0$. So, for either cases we can say.

For a random variable X and a constant x ,

$$X \geq x \text{ iff } e^{tX} \geq e^{tx} \text{ for } t > 0$$

$$X \leq x \text{ iff } e^{tX} \geq e^{tx} \text{ for } t < 0$$

$$P(X \geq x) = P(e^{tX} \geq e^{tx})$$

for $t > 0$ and

$$P(X \leq x) = P(e^{tX} \geq e^{tx})$$

for $t < 0$.

Using Markov's inequality, we can write

$$P(X \geq x) = P(e^{tX} \geq e^{tx}) \leq \frac{E[e^{tX}]}{e^{tx}} = e^{-tx} \phi_X(t)$$

for $t > 0$. Similarly, for $t < 0$, we can write

$$P(X \leq x) = P(e^{tX} \geq e^{tx}) \leq \frac{E[e^{tX}]}{e^{tx}} = e^{-tx} \phi_X(t)$$

Thus, we prove the two inequalities.

Now we want to show that for $t \geq 0$,

$$\Pr(X > (1 + \delta)\mu) \leq \frac{e^{\mu(e^t - 1)}}{e^{(1+\delta)t\mu}}, \quad t \geq 0, \delta > 0$$

where $\mu = E[X]$. For n independent Bernoulli random variable,

$$\mu = \sum_{i=1}^n p_i$$

Now, using the first part of the inequality derived above,

$$P(X \geq (1 + \delta)\mu) \leq e^{-t(1+\delta)\mu} \phi_X(t)$$

for $t > 0$. Now, we need to find the MGF of X .

$$\phi_X(t) = E[e^{tX}]$$

Now, for a Bernoulli random variable X_i with parameter p_i , we have

$$E[e^{tX_i}] = p_i e^t + (1 - p_i) = 1 + p_i(e^t - 1)$$

Since X is the sum of independent random variables. Using the property of MGFs that.

$$\phi_{X_1+X_2+\dots+X_N}(t) = \phi_{X_1}(t)\phi_{X_2}(t)\dots\phi_{X_N}(t)$$

we can write

$$\phi_X(t) = \prod_{i=1}^n (1 + p_i(e^t - 1))$$

Using the inequality $1 + x \leq e^x$, we get

$$\phi_X(t) \leq \prod_{i=1}^n e^{p_i(e^t - 1)} = e^{(e^t - 1) \sum_{i=1}^n p_i} = e^{\mu(e^t - 1)}$$

So, we can write

$$P(X \geq (1 + \delta)\mu) \leq e^{-t(1+\delta)\mu} e^{\mu(e^t - 1)}$$

or

$$P(X \geq (1 + \delta)\mu) \leq \frac{e^{\mu(e^t - 1)}}{e^{(1+\delta)t\mu}}$$

which is the required result. Hence, proven.

Question 6

Solution

T : Trial Number at which first heads appears

$$P(T = t) = (1 - p)^{t-1} p$$

For n independent coin tosses, Let $P(T = i) = T_i$ be the trial that first heads comes on the i^{th} coin. To find expectation of X , we use

$$E[T] = \sum_{i=1}^n i * P(T_i)$$

$$E[T] = \sum_{i=1}^n i(1 - p)^{i-1} p$$

This is an arithmetico-geometric series. Multiplying by $1-p$,

$$(1 - p)E[T] = \sum_{i=1}^n i(1 - p)^i p$$

Subtracting the two equations,

$$pE[T] = p(1 + (1 - p) + (1 - p)^2 + \dots + (1 - p)^{(n-1)} - n(1 - p)^n)$$

$$E[X] = \frac{1 - (1 - p)^n}{p} - n(1 - p)^n$$

$$E[X] = \frac{n}{p}(1 - (1 - p)^n(1 + np))$$
